Note: Within nine months of the publication of the mention of the grant of the European patent in the European Patent Bulletin, any person may give notice to the European Patent Office of opposition to that patent, in accordance with the Implementing Regulations. Notice of opposition shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

BACKGROUND

[0001] The present invention relates to a heating, ventilation, and air conditioning ("HVAC") system for a vehicle. More particularly, the present invention relates to a HVAC system that includes a refrigeration circuit and a controller programmed to adjust the refrigeration circuit based on a condition of a vehicle.

[0002] Generally, vehicle HVAC systems include a condenser or gas cooler, a compressor, an evaporator, and one or more fans that direct air across the condenser or gas cooler and/or the evaporator. Often, the main source of external noise for HVAC systems is generated by operation of the fans. External noise generated by the fans, or other components of the HVAC system, is most noticeable when the vehicle is stationary and an engine of the vehicle is idling.

[0003] EP1818238 discloses, in a railway vehicle, a fan for cooling and air conditioning which is controlled by signals to increase or reduce the fan speed according to the location of the train. The signals can be generated from the passenger announcement systems, track-side transmitters or a global positioning system (GPS). The fan speed is increased/decreased by one step when the temperature moves above and below a threshold value.

[0004] DE19911414 discloses a motor vehicle which has at least one door which receives opening (TA_2) and closing commands from an automatic door controller and an air conditioning system and/or heating-ventilation system, during whose operation an operationally required pressure difference exists between the desired air pressure within the vehicle and the external pressure. When a trigger signal (TA_1) is output for opening the door the pressure difference can be reduced to a predefined limit value; when a closing command and/or a closed signal is output the operationally desired internal air pressure is built up again after a period of time (Δt).

SUMMARY

[0005] In one embodiment, the invention according to claim 1 provides an air conditioning system for a vehicle that includes a propulsion system, a frame, a passenger compartment, and a door coupled to the frame. The air conditioning system includes a refrigeration circuit and a controller. The refrigeration circuit is operable to selectively control the temperature of the passenger compartment based on a sensed temperature within the passenger compartment. The refrigeration circuit includes an exterior heat exchanger that is supported by the frame, a first air moving device that is coupled to the exterior heat exchanger for directing air across the exterior heat exchanger, an interior heat exchanger supported by the frame and in fluid communication with the exterior heat exchanger, a second air moving device coupled to the interior heat exchanger for directing air across the interior

heat exchanger, and a compressor supported by the frame and in fluid communication with the exterior heat exchanger and the interior heat exchanger. The controller is operable to detect a condition of the vehicle that includes at least one of a position of the door, a location of the vehicle, and a load of the propulsion system. The controller is in communication with the refrigeration circuit to adjust the refrigeration circuit in response to the sensed temperature within the passenger compartment and the detected condition of the vehicle.

[0006] In yet another embodiment, the invention provides a method of operating a vehicle according to claim 8. The method includes providing a passenger compartment and an air conditioning system that has a refrigeration circuit in the vehicle. The refrigeration circuit is operable to control the temperature within the passenger compartment based on a sensed temperature within the passenger compartment. The method also includes initiating the air conditioning system and selectively conditioning the passenger compartment using the refrigeration circuit based on the sensed temperature within the passenger compartment, sensing a condition of the vehicle that includes at least one of a position of a door of the vehicle, a location of the vehicle, and a load of a propulsion system of the vehicle, and decreasing a speed of the refrigeration circuit in response to the vehicle condition.

[0007] Other aspects of the invention according to the appended claims will become apparent by consideration of the detailed description and accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] Fig. 1 is a perspective view of vehicle including a heating, ventilation, and air conditioning ("HVAC") system embodying the present invention.

[0009] Fig. 2 is a schematic view of the HVAC system of Fig. 1.

[0010] Fig. 3 is a flow chart diagram of the operation of one embodiment of the HVAC system.

DETAILED DESCRIPTION

[0011] Before any embodiments of the invention are explained in detail, it is to be understood that the invention is not limited in its application to the details of construction and the arrangement of components set forth in the following description or illustrated in the following drawings. The invention is capable of other embodiments and of being practiced or of being carried out in various ways. Also, it is to be understood that the phraseology and terminology used herein is for the purpose of description and should not be regarded as limiting. The use of "including," "comprising," or "having" and variations thereof herein is meant to encompass the items listed thereafter and equivalents thereof as well as additional items. Unless specified or limited otherwise, the terms "mounted," "connected," "supported," and "coupled" and variations

thereof are used broadly and encompass both direct and indirect mountings, connections, supports, and couplings. Further, "connected" and "coupled" are not restricted to physical or mechanical connections or couplings.

[0012] Fig. 1 shows an exemplary vehicle 10. In the embodiment illustrated in Fig. 1, the vehicle 10 is a mass-transit bus that carries passengers (not shown) to one or more destinations. In other embodiments, the vehicle 10 can be a school bus or other commercial vehicle that carries passengers. Hereinafter, the term "vehicle" shall be used to represent all such passenger vehicles, and shall not be construed to limit the scope of the invention solely to mass-transit buses.

[0013] Figs. 1 and 2 show that the vehicle 10 includes a frame 15, a passenger compartment 20 supported by the frame 15, wheels 25, and a compartment 30. The frame 15 includes doors 35 that are positioned on a side of the vehicle 10. As shown in Fig. 1, a first door 35 is located adjacent to a forward end of the vehicle 10, and a second door 35 is positioned on the frame 15 toward a rearward end of the vehicle 10. Each door 35 is movable between an open position and a closed position to selectively allow access to the passenger compartment 20.

[0014] As shown in Fig. 2, the vehicle 10 includes a door control device 40 that is coupled to each door 35 (only one shown). The door control device 40 is operable to move the doors 35 between the respective open positions and closed positions. In some embodiments, the door control device 40 is manually operated by an operator of the vehicle 10 to open and close the doors 35. In other embodiments, the door control device 40 can automatically open and close the doors 35 (e.g., via electronic signals, etc.). In still other embodiments, one door control device 40 can be provided for each door 35 of the vehicle 10 to independently open and close each door 35.

[0015] A door sensor 45 is coupled to each door 35 to sense when one or all doors 35 are in the open position, and to generate a signal indicative of the respective positions of the doors 35. For example, the door sensor 45 can generate a first signal indicative of one or all doors 35 in the open position, and can generate a second signal indicative of the doors 35 in the closed position.

[0016] Alternatively, no signal may be affirmatively generated by the door sensor 45 when the doors 35 are in the closed position (i.e., the sensor is "silent" when the doors 35 are in the closed position). However, the silence of the door sensor 45 when the doors 35 are closed can be indicative of the doors 35 in the closed position. In some embodiments, one door sensor 45 may be coupled to both or all doors 35. In other embodiments, a door sensor 45 may be provided for each door 35 to independently sense the position of the respective door 35.

[0017] The compartment 30 is located adjacent the rear end of the vehicle 10 (Fig. 1), and includes a propulsion system 50 that is coupled to the frame 15 to drive the wheels 25. In some embodiments, the compartment

30 can be located in other locations on the vehicle 10 (e.g., adjacent the forward end, etc.).

[0018] The propulsion system 50 (e.g., prime mover, engine, etc.) can be an internal combustion engine, or alternatively, a hybrid engine that includes an electrical power system coupled to an internal combustion engine. In other embodiments, the propulsion system 50 can be a fully electrical power system (e.g., battery assembly) without a corresponding internal combustion engine.

10 Hereinafter, the term "propulsion system" shall be used to represent all such propulsion systems, and shall not be construed to limit the scope of the invention solely to internal combustion engines.

[0019] Generally, the propulsion system 50 provides most, if not all of the power to vehicle components and accessories, in addition to powering the wheels 25, and includes an "off" state and an "on" state. Generally, the vehicle 10 is operable at one or more speeds, and the propulsion system 50 is the main driving component or mechanism for the speed that the vehicle 10 travels. The propulsion system 50 is further operable at relatively high loads and relatively low loads. The load that the propulsion system 50 is under is defined by the amount of work per time unit that must be provided by the propulsion system 50 to move and operate the vehicle 10. In other words, the load of the propulsion system 50 is defined by the amount of output power that must be provided by the propulsion system 50 to move and operate the vehicle 10. For example, the propulsion system 50 is under relatively high loads when the vehicle 10 is moving uphill or over rough terrain. The propulsion system 50 is under relatively low loads when the vehicle 10 is moving downhill, when the vehicle 10 is moving over relatively flat terrain, or when the propulsion system 50 is idling. Generally, a change in the load of the propulsion system 50 can be indicated by a change in the output power of the propulsion system 50 that is measured, for example, in kilowatts or horsepower.

[0020] A sensor 55 is coupled to the propulsion system 50 to sense a condition of the propulsion system 50, and to generate a signal indicative of the propulsion system condition. In some embodiments, the sensor 55 is configured to detect the load under which the propulsion system 50 is operating. In these embodiments, the sensor 55 generates a signal indicative of the propulsion system load. In other embodiments, the sensor 55 is configured to detect startup of the propulsion system 50 from the "off" state.

[0021] With continued reference to Fig. 2, the vehicle 10 also includes a vehicle positioning system 60 that is operable to detect a position or location of the vehicle 10. Generally, the vehicle positioning system 60 includes a vehicle position sensor 65 that determines the position of the vehicle 10 relative to an object or freestanding structure (e.g., a building, a bus-stop, etc.). The vehicle position sensor 65 is operable to determine the proximity or distance of the vehicle 10 to the freestanding structure, and is further operable to generate a signal indicative of

the proximity of the vehicle 10 relative to the freestanding structure. In some embodiments, the vehicle position sensor 65 can be a global positioning system sensor in communication with a global positioning system (not shown) that determines the location of the vehicle 10 relative to a freestanding structure. The vehicle positioning system 60 may also be used to determine the location of the vehicle 10 independent of the proximity of the vehicle 10 to a freestanding structure.

[0022] The vehicle 10 also includes a vehicle control system 70, a heating, ventilation, and air conditioning ("HVAC") system 75, and an interface or controller 80 in communication with the vehicle control system 70 and the HVAC system 75. The vehicle control system 70 can be located anywhere on the vehicle 10, and is in communication electrical and/or mechanical components (not shown) of the vehicle 10. The vehicle control system 70 is also in communication with the door control device 40, the propulsion system 50, and the vehicle positioning system 60 to receive the respective signals from the door sensor 45, the sensor 55, and the vehicle position sensor 65. Generally, the positions of the doors 35, the condition of the propulsion system 50, and the proximity of the vehicle 10 relative to a freestanding structure are defined as conditions of the vehicle 10. In some embodiments, additional vehicle conditions of the vehicle 10 may also be sensed by one or more sensors.

[0023] Fig. 1 shows that the HVAC system 75 is attached to the frame 15 on a roof 85 of the vehicle 10. Fig. 2 shows that the HVAC system 75 includes a refrigeration circuit 90 and an HVAC control system 95. The refrigeration circuit 90 is operable at various capacities, ranging from a zero capacity in an "off" state to a full capacity in an "on" state. The capacity of the refrigeration circuit 90 is the capacity at which the refrigeration circuit 90 is able to cool air that enters the passenger compartment 20.

[0024] A full capacity of the refrigeration circuit 90 corresponds to a first or normal mode of the HVAC system 75, and a reduced capacity (i.e., a capacity that is less than full capacity) of the refrigeration circuit 90 corresponds to a second or reduced noise mode of the HVAC system 75. Generally, the speed of one or more HVAC system components in the second mode are slower than the speed of the same components in the first mode, and operation of the HVAC system 75 in the second mode reduces perceived noise that emanates from the HVAC system 75. For example, when the HVAC system 75 operates at full capacity (i.e., in the first mode), the refrigeration circuit 90 operates at a speed that is generally necessary to maintain a predetermined temperature within the passenger compartment 20. When the HVAC system 75 operates at a reduced capacity (i.e., in the second mode), the refrigeration circuit 90 operates at a speed that is slower than the necessary speed to maintain the predetermined temperature of the passenger compartment 20. The HVAC system 75 is generally operable in the second mode only for a limited time based on the sensed vehicle conditions.

[0025] The first mode is indicative of a first, normal noise level of the HVAC system 75 that is based on noise produced by one or more of the refrigeration components. The second mode is indicative of a second, reduced noise level of the HVAC system 75. Thus, operation of the HVAC system 75 in the second mode is quieter than operation in the first mode, and which corresponds to reduced noise operation of the HVAC system 75. In other words, when the capacity of the refrigeration circuit 90 is reduced, the sound emitted by the HVAC system 75 is likewise reduced.

[0026] The refrigeration circuit 90 is a vehicle HVAC circuit that is operable to control a temperature of the passenger compartment 20 based on the temperature that is sensed within the passenger compartment 20 by one or more sensors (not shown). The refrigeration circuit includes an exterior heat exchanger 100, an interior heat exchanger 105, a compressor 110, a first air moving device 115, and a second air moving device 120. In the illustrated embodiment, the first and second air moving devices 115, 120 are fans. The refrigeration circuit 90 may also include additional components (not shown). A refrigerant flows through the refrigeration components to provide temperature-controlled air to the passenger compartment 20.

[0027] The speed of the refrigeration circuit 90 is defined as the speed of refrigerant flow through the exterior heat exchanger 100 and/or the interior heat exchanger 105. The speed of the refrigeration circuit 90 can be also defined as the speed of the compressor 110, the speed of the first air moving device 115, and/or the speed of the second air moving device 120, in addition to the speed of other components of the refrigeration circuit 90.

[0028] In some constructions, the exterior heat exchanger 100 cools heated refrigerant that flows from the compressor 110 in a cooling mode of the refrigeration circuit 90. The exterior heat exchanger 100 may include a gas cooler, or alternatively a condenser, depending on the type of refrigerant routed through the refrigeration circuit 90. In other constructions, the exterior heat exchanger 100 heats cooled refrigerant in a heating mode of the refrigeration circuit 90.

[0029] Although not shown, the interior heat exchanger 105 (e.g., evaporator, etc.) is in fluid communication with the exterior heat exchanger 100 to receive cooled refrigerant and to transfer heat from air passing over the interior heat exchanger 105 to the refrigerant prior to the air entering the passenger compartment 20. The compressor 110 is in fluid communication with the exterior heat exchanger 100 and the interior heat exchanger 105 to compress heated refrigerant received from the interior heat exchanger 105 and to provide refrigerant flow throughout the refrigeration circuit 90. The speed of the compressor 110 is variable based in part on a desired pressure of the refrigerant within the refrigeration circuit 90.

[0030] Generally, the first and second air moving devices 115, 120 include fans or blowers that direct airflow

across one or more components of the refrigeration circuit 90. The first air moving device 115 is coupled to the exterior heat exchanger 100, and the speed of the first air moving device 115 is variable based on desired airflow across the exterior heat exchanger 100. The first air moving device 115 generally directs air across the exterior heat exchanger 100 to cool heated, compressed refrigerant that flows from the compressor 110.

[0031] The second air moving device 120 is coupled to the interior heat exchanger 105, and the speed of the second air moving device 120 is variable based on desired airflow across the interior heat exchanger 105. The second air moving device 120 generally directs air across the interior heat exchanger 105 to cool air entering the passenger compartment 20 via heat transfer with cool refrigerant flowing through the interior heat exchanger 105.

[0032] The HVAC control system 95 is in communication with the compressor 110 to control compressor capacity, and is in communication with the first and second air moving devices 115, 120 to control the speed of the first and second air moving devices 115, 120. The HVAC control system 95 is operable to vary the refrigeration circuit 90 between an "off" state and an "on" state, and to further control the capacity of the refrigeration circuit 90 based in part on the desired temperature of the passenger compartment 20, and further based on ambient conditions adjacent to the HVAC system 75.

[0033] The HVAC control system 95 is also in communication with an evaporator sensor 125, a compressor sensor 130, and a refrigerant cooling device sensor 135. The HVAC control system 95 may also be in communication with other sensors (not shown) that are coupled to components of the refrigeration circuit 90. The evaporator sensor 125 is coupled to the interior heat exchanger 105 to sense a temperature of the refrigerant flowing through the interior heat exchanger 105, and to generate a signal indicative of the refrigerant temperature. In other embodiments, the evaporator sensor can sense the temperature of air flowing over the interior heat exchanger 105. In still other embodiments, the evaporator can sense a pressure of refrigerant that flows through the interior heat exchanger 105.

[0034] The compressor sensor 130 is coupled to the compressor 110 to sense a pressure of refrigerant that flows through the compressor 110. In some embodiments, the compressor sensor 130 can monitor the pressure of the refrigerant that enters the compressor 110 (i.e., the suction pressure). In other embodiments, the compressor sensor 130 can monitor the pressure of refrigerant that exits the compressor 110 (i.e., the discharge pressure). In still other embodiments, the compressor sensor 130 may be configured to sense the discharge pressure and the suction pressure of the refrigerant flowing through the compressor 110.

[0035] The refrigerant cooling device sensor 135 is coupled to the exterior heat exchanger 100 to sense a temperature of refrigerant exiting the exterior heat ex-

changer 100, and to generate a signal indicative of the sensed temperature. In some embodiments, the refrigerant cooling device sensor 135 can be located in a refrigeration line (not shown) that is proximate to and downstream of the exterior heat exchanger 100.

[0036] The controller 80 is disposed in the vehicle 10, and generally can be located anywhere on the vehicle 10. The controller 80 is in communication with the vehicle control system 70 and the HVAC system 75 to monitor conditions of the vehicle 10 and the HVAC system 75, and to control the HVAC system 75 in response to the sensed temperature within the passenger compartment 20 and the sensed vehicle conditions. In some embodiments, the controller 80 can be a stand-alone controller 80 in addition to the vehicle control system 70 and the HVAC control system 95. In other embodiments, the vehicle control system 70 and/or the HVAC control system 95 can be a part of or subsumed in the controller 80.

[0037] The vehicle conditions sensed by the door sensor 45, the sensor 55, and the vehicle position sensor 65 are communicated to the controller 80 via the vehicle control system 70 to enable the controller 80 to selectively vary the HVAC system 75 between the first mode and the second mode via the HVAC control system 95.

[0038] The conditions of the refrigeration circuit 90 sensed by the evaporator sensor 125, the compressor sensor 130, and the refrigerant cooling device sensor 135 are communicated to the controller 80 via the HVAC control system 95 to enable the controller 80 to monitor the conditions and capacity of the refrigeration circuit 90.

[0039] In operation, the controller 80 receives the signals indicative of the vehicle conditions and the signals indicative of the conditions of the refrigeration circuit 90 from the respective sensors, and monitors and controls the HVAC system 75 based on these signals. The controller 80 operates the HVAC system 75 in the second mode when the sensed vehicle conditions indicate that the vehicle 10 is stopped, the propulsion system 50 is operating under a relatively high load, and/or the vehicle 10 is located in close proximity to a freestanding structure.

[0040] The proximity of the vehicle 10 relative to the freestanding structure is determined by the vehicle positioning system 60, and is communicated to the controller 80 via the vehicle control system 70. Generally, the proximity of the vehicle 10 relative to the freestanding structure is based on the distance between the vehicle 10 and the freestanding structure. The vehicle position sensor 65 detects the position of the vehicle 10 and generates a signal that is indicative of the proximity of the vehicle 10 relative to the freestanding structure. When the distance between the vehicle 10 and the freestanding structure is less than or equal to a predetermined distance (e.g., 10 meters, 50 meters, etc.), the controller 80 determines that the vehicle 10 is in close proximity to the freestanding structure. When the distance between the vehicle 10 and the freestanding structure is greater than the predetermined distance, the controller 80 determines

that the vehicle 10 is not in close proximity to the free-standing structure and is located away from the structure.

[0040] In some embodiments, the vehicle 10 may be considered in close proximity to the freestanding structure based on the distance between the vehicle 10 and the freestanding structure, and further based on the time period that the vehicle 10 is located at a distance that is less than or equal to the predetermined distance from the freestanding structure. In other embodiments, the controller 80 may determine that the vehicle 10 is in close proximity to the freestanding structure when the distance between the vehicle 10 and the freestanding structure is less than the predetermined distance, and that the vehicle is not in close proximity when the distance is greater than or equal to the predetermined distance.

[0041] Fig. 3 shows one embodiment of operation of the vehicle 10 using the controller 80. The controller 80 initiates the HVAC system 75 at step 200 after the propulsion system 50 has been started. In some embodiments, the HVAC system 75 may be self-initiated by the HVAC control system 95 after startup of the propulsion system 50. After initiation, the HVAC system 75 is operated in the first mode. The flow of refrigerant through the refrigeration circuit 90 and the capacity of the refrigeration circuit 90 can be controlled by the controller 80 and/or the HVAC control system 95 based on the signals received from the evaporator sensor 125, the compressor sensor 130, and the refrigerant cooling device sensor 135, and further based on the signals indicative of the vehicle conditions (e.g., sensed temperature) and the desired conditions (e.g., desired temperature) of the passenger compartment 20.

[0042] At step 205, the vehicle conditions are sensed by the door sensor 45, the sensor 55, and the vehicle position sensor 65. The controller 80 receives the signals indicative of the respective vehicle conditions that are generated by the sensors 45, 55, 65. At step 210, the controller 80 determines whether the HVAC system 75 should be operated in the second mode. Generally, the signals received by the controller 80 indicating that the HVAC system 75 should be operated in the second mode (e.g., one or more doors 35 are open, the vehicle 10 is located in close proximity to a freestanding structure, the propulsion system 50 is operating under a relatively high load, the vehicle is moving at a relatively slow speed, etc.) are signals indicative of a first vehicle condition. The signals received by the controller 80 indicating that the HVAC system 75 should be operated in the first mode (e.g., the doors 35 are closed, the vehicle is a predetermined distance from the freestanding structure, the propulsion system 50 is operating under a relatively low load, etc.) are generally signals indicative of a second vehicle condition.

[0043] At step 215, the HVAC system 75 continues to be operated in the first mode by the controller 80 when all of the sensed vehicle conditions are indicative of a second vehicle condition (i.e., "No" at step 210). Operation of the vehicle 10 then returns to step 205.

[0044] At step 220, the controller 80 determines whether the refrigerant pressure (e.g., the discharge pressure, the suction pressure) sensed by the compressor sensor 130 is greater than a predetermined pressure when one or more of the sensed vehicle conditions indicate that the HVAC system 75 should be operated in the second mode (i.e., "Yes" at step 210). If the refrigerant pressure sensed by the compressor sensor 130 is greater than the predetermined pressure (i.e., "Yes" at step 220), operation of

the HVAC system 75 returns to step 215 and the controller 80 continues to operate the HVAC system 75 in the first mode regardless of the sensed vehicle conditions. In some embodiments, the HVAC system 75 can continue to be operated in the first mode when the refrigerant discharge pressure is equal to or greater than the predetermined pressure.

[0045] Generally, the controller 80 monitors the sensed refrigerant pressure to provide an override control to operation of the HVAC system 75 in the second mode. The controller 80 overrides the signals that indicate the HVAC system 75 should be operated in the second mode when the signal from the compressor sensor 130 indicates that the refrigerant pressure exceeds the predetermined pressure. This override protects the structural integrity of the refrigeration circuit 90 and prevents conditions in the passenger compartment 20 from becoming undesirable.

[0046] If the refrigerant pressure sensed by the compressor sensor 130 at step 220 is less than or equal to the predetermined pressure (i.e., "No" at step 220), the controller 80 varies the HVAC system 75 from the first mode to the second mode at step 225 to decrease the speed of the refrigeration circuit 90 such that the noise output of the HVAC system 75 is reduced. The speed of the refrigeration circuit 90 is decreased by decreasing the speed of one or more of the refrigeration components (e.g., the compressor 110, the first air moving device 115, the second air moving device 120, etc.).

[0047] In some embodiments, the controller 80 decreases the speed of the compressor 110, the first air moving device 115, or the second air moving device 120 in response to the vehicle conditions indicating that the HVAC system 75 should be operated in the second mode. For example, the controller 80 can be programmed to decrease the speed of the first air moving device 115 to reduce the noise output of the HVAC system 75 without decreasing the speed of the compressor 110 or the second air moving device 120. Similarly, the controller 80 may be programmed to decrease the speed of the compressor 110, or alternatively the second air moving device 120, to reduce the noise output of the HVAC system 75 without decreasing the speed of the other refrigeration components.

[0048] In other embodiments, the controller 80 may decrease the speed of the compressor 110, the first air moving device 115, and the second air moving device 120 (i.e., all three components) to reduce the noise output of the HVAC system 75. In still other embodiments, the con-

troller 80 may be programmed to decrease the speed of the compressor 110, the first air moving device 115, and/or the second air moving device 120. For example, the controller 80 may decrease the speed of the first air moving device 115 and the second air moving device 120, but not the speed of the compressor 110. Instead, the controller 80 may decrease the speed of the compressor 110 and the first air moving device 115, but not the speed of the second air moving device 120. Similarly, the controller 80 may decrease the speed of the compressor 110 and the second air moving device 120 without decreasing the speed of the first air moving device 115. Generally, the controller 80 can be programmed to decrease the speed of any combination of the compressor 110, the first air moving device 115, and the second air moving device 120 to facilitate a reduction of noise output by the HVAC system 75. In other embodiments, the controller 80 may be programmed to decrease the speed of other components of the refrigeration circuit 90.

[0049] At step 230, the vehicle conditions are again sensed by the door sensor 45, the sensor 55, and the vehicle position sensor 65. The signals indicative of the respective vehicle conditions are received by the controller 80, which determines at step 235 whether all of the sensed vehicle conditions indicate that the HVAC system 75 should be operated in the first mode. If one or more of the vehicle conditions indicate that the HVAC system 75 should continue to operate in the second mode (i.e., "No" at step 235), the controller 80 again determines whether the refrigerant pressure sensed by the compressor sensor 130 is greater than the predetermined pressure at step 240.

[0050] At step 245, the HVAC system 75 continues to be operated by the controller 80 in the second mode when the refrigerant pressure sensed by the compressor sensor 130 is less than or equal to the predetermined pressure (i.e., "No" at step 240). The refrigeration circuit 90 continues to be operated at the decreased speed such that the noise output of the HVAC system 75 is continues to be quieter than the noise output when the HVAC system 75 is operated in the first mode. Operation of the vehicle 10 then returns to step 230.

[0051] If the refrigerant pressure sensed by the compressor sensor 130 is greater than the predetermined pressure (i.e., "Yes" at step 240), the controller 80 varies the HVAC system 75 from the second mode to the first mode at step 250 to increase the speed of the refrigeration circuit 90 to a full capacity speed. The speed of the refrigeration circuit 90 is increased by increasing the speed of one or more of the refrigeration components (e.g., the compressor 110, the first air moving device 115, the second air moving device 120, etc.). In some embodiments, the HVAC system 75 can be varied to operation in the first mode when the refrigerant discharge pressure is equal to or greater than the predetermined pressure.

[0052] When all of the sensed vehicle conditions indicate that the HVAC system 75 should be operated in the first mode (i.e., "Yes" at step 235), the controller 80 varies

the HVAC system 75 from the second mode to the first mode at step 250. The switching of the HVAC system 75 from the second mode to the first mode increases the speed of the refrigeration circuit 90. The increased speed of the refrigeration circuit 90, relative to the speed at which the refrigeration circuit 90 had been operating with the HVAC system 75 in the second mode, allows the HVAC system 75 to operate at full capacity. In some embodiments, the controller 80 may initiate a predetermined delay in response to the sensed vehicle condition and prior to varying the HVAC system 75 from the second mode to the first mode. Generally, the speed of the refrigeration circuit 90 is increased by increasing the speed of the refrigeration component or components that were previously operated at a decreased speed.

[0053] For example, if the speed of the compressor 110 was previously decreased such that the HVAC system 75 is operating in the second mode, varying the HVAC system 75 from the second mode to the first mode increases the speed of the compressor 110. If the speed of the first air moving device 115 had been previously decreased, varying the HVAC system 75 from the second mode to the first mode increases the speed of the first air moving device 115. If the speed of the second air moving device 120 had been previously decreased, varying the HVAC system 75 from the second mode to the first mode increases the speed of the second air moving device 120. If the speed of two or more components (e.g., the compressor 110 and the first air moving device 115, etc.) had been previously decreased, varying the HVAC system 75 from the second mode to the first mode increases the speed of these components.

[0054] In some embodiments, each signal indicative of a vehicle condition is independent from the remaining signals indicative of the vehicle conditions such that the controller 80 selectively operates the HVAC system 75 in the second mode in response to one vehicle condition regardless or independent of the other sensed vehicle conditions. Generally, when the respective independent signal indicative of the first vehicle condition has been generated (e.g., one or more of the doors 35 are in the open position, the vehicle 10 is located in close proximity to a freestanding structure, the propulsion system 50 is under a high load, or the vehicle 10 is operating at a relatively slow speed, etc.), the controller 80 varies the HVAC system 75 from the first mode to the second mode regardless of other signals. When the respective independent signal indicative of the first vehicle condition has cleared (e.g., the doors 35 are closed, the vehicle 10 is no longer located in close proximity to a freestanding structure, the propulsion system 50 is operating under a high load, or the vehicle 10 is operating at a relatively fast speed, etc.), the controller 80 varies the HVAC system 75 from the second mode to the first mode regardless of other signals. In other words, when the respective independent signal indicative of the second vehicle condition is generated, the controller 80 varies the HVAC system 75 from the second mode to the first mode regardless

of other signals.

[0055] For example, when the door sensor 45 senses one door 35 in the open position (i.e., the first vehicle condition), the controller 80 can vary the HVAC system 75 from the first mode to the second mode. When the previously opened door 35 is sensed by the door sensor 45 in the closed position (i.e., the second vehicle condition), the door sensor 45 generates a signal indicative of the changed condition. The controller 80 receives the signal indicative of the door 35 in the closed position and can vary the HVAC system 75 from the second mode to the first mode regardless of the signals from the sensor 55 and the vehicle position sensor 65.

[0056] Likewise, the controller 80 can vary the HVAC system 75 from the first mode to the second mode independent of the signals from the door sensor 45 and the vehicle position sensor 65 when the sensor 55 senses that the propulsion system 50 has just been started or is operating under a high load, or that the vehicle 10 is operating at a relatively slow speed. The controller 80 can vary the HVAC system 75 from the second mode to the first mode regardless of other sensed vehicle conditions when the sensor 55 senses that propulsion system 50 has warmed up or is operating at a relatively low load, or the vehicle 10 is operating at a relatively fast speed.

[0057] With regard to sensing the location of the vehicle 10 using the vehicle position sensor 65, the controller 80 can vary the HVAC system 75 from the first mode to the second mode when the vehicle 10 is sensed to be in close proximity to a freestanding structure independent of the signals from the door sensor 45 and the sensor 55. The controller 80 can vary the HVAC system 75 from the second mode to the first mode regardless of other sensed vehicle conditions when the vehicle position sensor 65 senses that the vehicle 10 is no longer in close proximity to the freestanding structure.

[0058] In other embodiments, the signals indicative of the respective vehicle conditions work in combination with each other such that the controller 80 selectively varies the HVAC system 75 between the first mode and the second mode based on the various combinations of the signals. In these embodiments, when at least one sensor 45, 55, 65 senses a vehicle condition indicative of a first vehicle condition, the controller 80 varies the HVAC system 75 from the first mode to the second mode. Any combination of the signals indicative of the first vehicle condition cause the controller 80 to operate the HVAC system 75 in the second mode. Thus, if one, two, or more sensors detect a first vehicle condition, the HVAC system 75 is operated in the second mode. However, in these embodiments, the controller 80 does not vary the HVAC system 75 from the second mode to the first mode until all signals indicative of the first vehicle conditions have cleared (i.e., all sensors generate signals indicative of a second vehicle condition).

[0059] In still other embodiments, when two or more sensors 45, 55, 65 generate signals indicative of respective first vehicle conditions, the controller 80 can vary the

HVAC system 75 from the first mode to the second mode. In these embodiments, the controller 80 can vary the HVAC system 75 from the second mode to the first mode when any or all of the signals indicative of the first vehicle condition have cleared. In other words, operation of the HVAC system 75 is changed from the second mode to the first mode when at least one of the sensors that previously generated a signal indicative of a first vehicle condition generates a signal indicative of a second vehicle condition.

[0060] In hybrid vehicle applications, the sensor 55 senses the load of the propulsion system 50 and the controller 80 determines whether the propulsion system load is above a predetermined value that corresponds to the power necessary for the vehicle 10 to adequately operate (e.g., move up a hill, etc.). When the propulsion system 50 needs additional power (e.g., from a battery pack, etc.) to facilitate adequate movement of the vehicle 10, the controller 80 can provide additional power to the propulsion system 50 by reducing power consumption of other components of the vehicle 10. For example, the controller 80 can decrease the speed of the refrigeration circuit 90 by operating the HVAC system 75 in the second mode, which decreases power consumption by the HVAC system 75 and allows a portion of the power originally supplied to the HVAC system 75 to be directed to the propulsion system 50 so that the propulsion system 50 has adequate power to operate. When the propulsion system 50 no longer needs the additional power, the controller 80 can direct the power back to the HVAC system 75 and operate the HVAC system 75 in the first mode.

[0061] The scope of the invention is defined in the following claims.

Claims

1. A heating, ventilation, and air conditioning ("HVAC") system (75) for a vehicle (10) including a propulsion system (50), a frame (15), a passenger compartment (20), and a door (35) coupled to the frame, the HVAC system (75) comprising:

a refrigeration circuit (90) operable to selectively control the temperature of the passenger compartment (20) based on a sensed temperature within the passenger compartment, the refrigeration circuit (90) including

an exterior heat exchanger (100) supported by the frame (15), a first air moving device (115) coupled to the exterior heat exchanger (100) for directing air across the exterior heat exchanger, an interior heat exchanger (105) supported by the frame (15) and in fluid communication with the exterior heat exchanger (100),

a second air moving device (120) coupled to the interior heat exchanger (105) for directing air across the interior heat exchanger, and

- a compressor (110) supported by the frame (15) and in fluid communication with the exterior heat exchanger (100) and the interior heat exchanger (105); and
 a controller (80) operable to detect a condition of the vehicle (10), the vehicle condition including at least one of a position of the door (35), a location of the vehicle (10), and a load of the propulsion system (50), the controller (80) in communication with the refrigeration circuit (90) and programmed to adjust the refrigeration circuit in response to the sensed temperature of the passenger compartment (20) and the detected condition of the vehicle (10),
 wherein the controller (80) is programmed to decrease a speed of at least one of the first air moving device (115), the second air moving device (120), and the compressor (110) in response to detection of a first condition of the vehicle (10), and wherein the controller (80) is programmed to increase the speed of at least one of the first air moving device (115), the second air moving device (120), and the compressor (110) that was previously operated at a decreased speed in response to detection of a second condition of the vehicle (10), and
 wherein the first vehicle condition includes the door (35) detected in an open position, and wherein the second vehicle condition includes the door (35) detected in a closed position.
2. The HVAC system of claim 1, wherein the first vehicle condition further includes the location of the vehicle (10) detected in close proximity with a freestanding structure, and wherein the second vehicle condition includes the location of the vehicle (10) detected at least a predetermined distance from the freestanding structure.
3. The HVAC system of claim 1, wherein the first vehicle condition further includes the propulsion system load detected above a first predetermined value, and wherein the second vehicle condition includes the propulsion system load detected below a second predetermined value
4. The HVAC system of claim 1, wherein the controller (80) is programmed to initiate a predetermined delay in response to the second vehicle condition and prior to increasing the speed of at least one of the first air moving device (115), the second air moving device (120), and the compressor (110) that was previously operated at a decreased speed.
5. The HVAC system of claim 1, wherein the vehicle (10) includes a global positioning system sensor.
6. The HVAC system of claim 1, wherein the controller (80) is programmed to initiate a predetermined delay in response to the vehicle condition and prior to increasing the speed of at least one of the first air moving device (115), the second air moving device (120), and the compressor (110).
7. The HVAC system of claim 1, wherein the controller (80) is programmed increase the speed of at least one of the first air moving device (115), the second air moving device (120), and the compressor (110) regardless of the vehicle condition in response to a refrigerant pressure of the refrigeration circuit above a predetermined pressure.
8. A method of operating a vehicle (10), the method comprising:
- providing a passenger compartment (20) and a heating, ventilation, and air conditioning ("HVAC") system (75) in the vehicle, the HVAC system including a refrigeration circuit (90) operable to control the temperature within the passenger compartment (20) based on a sensed temperature within the passenger compartment (20), the refrigeration circuit (90) having an exterior heat exchanger (100), a first air moving device (115) for directing air across the exterior heat exchanger, an interior heat exchanger (105) in fluid communication with the exterior heat exchanger, a second air moving device (120) for directing air across the interior heat exchanger, and a compressor (110);
 initiating the HVAC system (75);
 detecting a condition of the vehicle (10) including detecting at least one of a position of a door (35) of the vehicle, a location of the vehicle, and a load of a propulsion system (50) of the vehicle, wherein a first vehicle condition includes the door (35) detected in an open position, and wherein the second vehicle condition includes the door detected in a closed position;
 adjusting the refrigeration circuit (90) in response to the sensed temperature within the passenger compartment (20) and the detected condition of the vehicle (10);
 decreasing a speed of at least one of the first air moving device (115), the second air moving device (120), and the compressor (110) in response to detection of the first condition of the vehicle (10); and
 increasing the speed of the at least one of the first air moving device (115), the second air moving device (120), and the compressor (110) that was previously operated at a decreased speed in response to detection of the second condition of the vehicle (10).
9. The method of claim 8, further comprising reducing

a noise output of the HVAC system (75) by decreasing a speed of the refrigeration circuit (90) in response to the vehicle condition.

10. The method of claim 8, further comprising sensing the location of the vehicle (10) relative to a freestanding structure; decreasing a speed of the refrigeration circuit (90) in response to the location of the vehicle (10) in close proximity with the freestanding structure; increasing the speed of the refrigeration circuit (90) in response to the location of the vehicle (10) at least a predetermined distance from the freestanding structure. 15
11. The method of claim 8, further comprising decreasing at least one of a speed of the first air moving device (115), the second air moving device (120), and the compressor (110) in response to the vehicle condition.. 20
12. The method of claim 8, further comprising sensing a refrigerant pressure of the refrigeration circuit (90); and operating the refrigeration circuit (90) at a full capacity speed regardless of the vehicle condition in response to the refrigerant pressure above a predetermined pressure. 25
13. The method of claim 8, further comprising decreasing the speed of the refrigeration circuit (90) in response to the vehicle condition; and increasing a speed of the refrigeration circuit (90) in response to an additional condition of the vehicle (10). 30
14. The method of claim 13, further comprising initiating a predetermined delay in response to the additional vehicle condition and prior to increasing the speed of the refrigeration circuit (90). 40
15. The method of claim 8, further comprising sensing a load of the propulsion system (50); decreasing a speed of the refrigeration circuit (90) in response to the propulsion system (50) load being sensed above a first predetermined value; and increasing the speed of the refrigeration circuit (90) in response to the propulsion system (50) load being sensed below a second predetermined value. 45
- 50

Patentansprüche

1. Heizungs-, Lüftungs- und Klima- ("HLK") Anlage (75) für ein Fahrzeug (10), das eine Antriebsanlage (50), einen Rahmen (15), einen Fahrgastraum (20) und eine an den Rahmen gekoppelte Tür (35) einschließt, wobei die HLK-Anlage (75) Folgendes um-
- 55

fasst:

einen Kühlkreislauf (90), der funktionsfähig ist, um auf der Grundlage einer abgeführten Temperatur innerhalb des Fahrgastraumes selektiv die Temperatur des Fahrgastraumes (20) zu regeln, wobei der Kühlkreislauf (90) Folgendes einschließt:

einen äußeren Wärmeaustauscher (100), der durch den Rahmen (15) getragen wird, eine erste Luftbewegungseinrichtung (115), die an den äußeren Wärmeaustauscher (100) gekoppelt ist, um Luft über den äußeren Wärmeaustauscher zu leiten, einen inneren Wärmeaustauscher (105), der durch den Rahmen (15) getragen wird und in Fluidverbindung mit dem äußeren Wärmeaustauscher (100) steht, eine zweite Luftbewegungseinrichtung (120), die an den inneren Wärmeaustauscher (105) gekoppelt ist, um Luft über den inneren Wärmeaustauscher zu leiten, und einen Verdichter (110), der durch den Rahmen (15) getragen wird und in Fluidverbindung mit dem äußeren Wärmeaustauscher (100) und dem inneren Wärmeaustauscher (105) steht, und ein Steuergerät (80), das funktionsfähig ist, um einen Zustand des Fahrzeugs (10) zu erfassen, wobei der Fahrzeugzustand wenigstens eines von einer Stellung der Tür (35), einer Position des Fahrzeugs (10) und einer Last der Antriebsanlage (50) einschließt, wobei das Steuergerät (80) in Verbindung mit dem Kühlkreislauf (90) steht und dafür programmiert ist, den Kühlkreislauf als Reaktion auf die abgeführte Temperatur des Fahrgastraumes (20) und den erfassten Zustand des Fahrzeugs (10) einzustellen, wobei das Steuergerät (80) dafür programmiert ist, als Reaktion auf das Erfassen eines ersten Zustandes des Fahrzeugs (10) eine Geschwindigkeit wenigstens eines von der ersten Luftbewegungseinrichtung (115), der zweiten Luftbewegungseinrichtung (120) und dem Verdichter (110) zu vermindern, und wobei das Steuergerät (80) dafür programmiert ist, als Reaktion auf das Erfassen eines zweiten Zustandes des Fahrzeugs (10) die Geschwindigkeit wenigstens eines von der ersten Luftbewegungseinrichtung (115), der zweiten Luftbewegungseinrichtung (120) und dem Verdichter (110), das zuvor mit einer verminderten Geschwindigkeit betrieben wurde, zu steigern, und

- wobei der erste Fahrzeugzustand einschließt, dass die Tür (35) in einer offenen Stellung erfasst wird, und wobei der zweite Fahrzeugzustand einschließt, dass die Tür (35) in einer geschlossenen Stellung erfasst wird. 5
2. HLK-Anlage nach Anspruch 1, wobei der erste Fahrzeugzustand ferner einschließt, dass die Position des Fahrzeugs (10) in enger Nähe zu einer freistehenden Struktur erfasst wird, und wobei der zweite Fahrzeugzustand einschließt, dass die Position des Fahrzeugs in wenigstens einer vorbestimmten Entfernung von der freistehenden Struktur erfasst wird. 10
3. HLK-Anlage nach Anspruch 1, wobei der erste Fahrzeugzustand ferner einschließt, dass die Antriebsanlagenlast oberhalb eines ersten vorbestimmten Wertes erfasst wird, und wobei der zweite Fahrzeugzustand einschließt, dass die Antriebsanlagenlast unterhalb eines zweiten vorbestimmten Wertes erfasst wird. 15 20
4. HLK-Anlage nach Anspruch 1, wobei das Steuergert (80) dafür programmiert ist, als Reaktion auf den zweiten Fahrzeugzustand und vor dem Steigern der Geschwindigkeit wenigstens eines von der ersten Luftbewegungseinrichtung (115), der zweiten Luftbewegungseinrichtung (120) und dem Verdichter (110), das zuvor mit einer verminderten Geschwindigkeit betrieben wurde, eine vorbestimmte Verzögerung einzuleiten. 25 30
5. HLK-Anlage nach Anspruch 1, wobei das Fahrzeug (10) einen Global-Positioning-System-Sensor einschließt. 35
6. HLK-Anlage nach Anspruch 1, wobei das Steuergert (80) dafür programmiert ist, als Reaktion auf den Fahrzeugzustand und vor dem Steigern der Geschwindigkeit wenigstens eines von der ersten Luftbewegungseinrichtung (115), der zweiten Luftbewegungseinrichtung (120) und dem Verdichter (110) eine vorbestimmte Verzögerung einzuleiten. 40 45
7. HLK-Anlage nach Anspruch 1, wobei das Steuergert (80) dafür programmiert ist, ungeachtet des Fahrzeugzustandes als Reaktion auf einen Kühlmitteldruck des Kühlkreislaufs oberhalb eines vorbestimmten Drucks die Geschwindigkeit wenigstens eines von der ersten Luftbewegungseinrichtung (115), der zweiten Luftbewegungseinrichtung (120) und dem Verdichter (110) zu steigern. 50
8. Verfahren zum Betreiben eines Fahrzeugs (10), wobei das Verfahren Folgendes umfasst:
das Bereitstellen eines Fahrgastrumes (20)
- und einer Heizungs-, Lüftungs- und Klima ("HLK")-Anlage (75) in dem Fahrzeug, wobei die HLK-Anlage einen Kühlkreislauf (90), der funktionsfähig ist, um auf der Grundlage einer abgefühlten Temperatur innerhalb des Fahrgastrumes (20) die Temperatur des Fahrgastrumes (20) zu regeln, einschließt, wobei der Kühlkreislauf (90) einen äußeren Wärmeaustauscher (100), eine erste Luftbewegungseinrichtung (115), um Luft über den äußeren Wärmeaustauscher zu leiten, einen inneren Wärmeaustauscher (105) in Fluidverbindung mit dem äußeren Wärmeaustauscher, eine zweite Luftbewegungseinrichtung (120), um Luft über den inneren Wärmeaustauscher zu leiten, und einen Verdichter (110) aufweist,
das Starten der HKL-Anlage (75),
das Erfassen eines Zustandes des Fahrzeugs (10), was das Erfassen wenigstens eines von einer Stellung einer Tür (35) des Fahrzeugs, einer Position des Fahrzeugs und einer Last einer Antriebsanlage (50) des Fahrzeugs einschließt, wobei der erste Fahrzeugzustand einschließt, dass die Tür (35) in einer offenen Stellung erfasst wird, und wobei der zweite Fahrzeugzustand einschließt, dass die Tür in einer geschlossenen Stellung erfasst wird,
das Einstellen des Kühlkreislaufs (90) als Reaktion auf die abgeühlte Temperatur innerhalb des Fahrgastrumes (20) und den erfassten Zustand des Fahrzeugs (10),
das Vermindern einer Geschwindigkeit wenigstens eines von der ersten Luftbewegungseinrichtung (115), der zweiten Luftbewegungseinrichtung (120) und dem Verdichter (110) als Reaktion auf das Erfassen des ersten Zustandes des Fahrzeugs (10), und
das Steigern der Geschwindigkeit des wenigstens einen von der ersten Luftbewegungseinrichtung (115), der zweiten Luftbewegungseinrichtung (120) und dem Verdichter (110), das zuvor mit einer verminderten Geschwindigkeit betrieben wurde, als Reaktion auf das Erfassen des zweiten Zustandes des Fahrzeugs (10). 55
9. Verfahren nach Anspruch 8, das ferner das Verringen einer Geräuschabgabe der HKL-Anlage (75) durch das Vermindern einer Geschwindigkeit des Kühlkreislaufs (90) als Reaktion auf den Fahrzeugzustand umfasst.
10. Verfahren nach Anspruch 8, das ferner Folgendes umfasst:
das Abfühlen der Position des Fahrzeugs (10) im Verhältnis zu einer freistehenden Struktur,
das Vermindern einer Geschwindigkeit des Kühlkreislaufs (90) als Reaktion darauf, dass die

	Revendications
Position des Fahrzeugs (10) in enger Nähe zu der freistehenden Struktur erfasst wird, das Steigern der Geschwindigkeit des Kühlkreislaufs (90) als Reaktion darauf, dass die Position des Fahrzeugs (10) in wenigstens einer vorbestimmten Entfernung von der freistehenden Struktur erfasst wird.	5
11. Verfahren nach Anspruch 8, das ferner das Vermindern der Geschwindigkeit wenigstens eines von der ersten Luftbewegungseinrichtung (115), der zweiten Luftbewegungseinrichtung (120) und dem Verdichter (110) als Reaktion auf den Fahrzeugzustand umfasst.	10
12. Verfahren nach Anspruch 8, das ferner Folgendes umfasst: das Abfühlen eines Kühlmitteldrucks des Kühlkreislaufs (90) und das Betreiben des Kühlkreislaufs (90) bei einer Geschwindigkeit mit voller Leistung ungeachtet des Fahrzeugzustandes als Reaktion darauf, dass der Kühlmitteldruck oberhalb eines vorbestimmten Drucks liegt.	15 20 25
13. Verfahren nach Anspruch 8, das ferner Folgendes umfasst: das Vermindern der Geschwindigkeit des Kühlkreislaufs (90) als Reaktion auf den Fahrzeugzustand und das Steigern der Geschwindigkeit des Kühlkreislaufs (90) als Reaktion auf einen zusätzlichen Zustand des Fahrzeugs (10).	30 35
14. Verfahren nach Anspruch 13, das ferner das Einleiten einer vorbestimmten Verzögerung als Reaktion auf den zusätzlichen Fahrzeugzustand und vor dem Steigern der Geschwindigkeit des Kühlkreislaufs (90) umfasst.	40
15. Verfahren nach Anspruch 8, das ferner Folgendes umfasst: das Abfühlen einer Last der Antriebsanlage (50), das Vermindern einer Geschwindigkeit des Kühlkreislaufs (90) als Reaktion darauf, dass die Antriebsanlagenlast (50) oberhalb eines ersten vorbestimmten Wertes erfasst wird, und das Steigern der Geschwindigkeit des Kühlkreislaufs (90) als Reaktion darauf, dass die Antriebsanlagenlast (50) unterhalb eines zweiten vorbestimmten Wertes erfasst wird.	45 50 55
	1. Système de chauffage, de ventilation et de conditionnement d'air (« HVAC ») (75) pour un véhicule (10), englobant un système de propulsion (50), un cadre (15), un habitacle (20) et une porte (35) accouplée au cadre, le système HVAC (75) comprenant : un circuit de réfrigération (90), servant à contrôler sélectivement la température de l'habitacle (20) sur la base d'une température détectée dans l'habitacle, le circuit de réfrigération (90) englobant un échangeur de chaleur externe (100) supporté par le cadre (15) ; un premier dispositif de déplacement d'air (115), accouplé à l'échangeur de chaleur externe (100), pour diriger l'air à travers l'échangeur de chaleur externe ; un échangeur de chaleur interne (105), supporté par le cadre (15) et en communication de fluide avec l'échangeur de chaleur externe (100) ; un deuxième dispositif de déplacement d'air (120), accouplé à l'échangeur d'air interne (105), pour diriger l'air à travers l'échangeur de chaleur interne ; et un compresseur (110), supporté par le cadre (15) et en communication de fluide avec l'échangeur de chaleur externe (100) et l'échangeur de chaleur interne (105) ; et un moyen de commande (80), servant à détecter une condition du véhicule (10), la condition du véhicule englobant au moins un critère, une position de la porte (35), un emplacement du véhicule (10) et une charge du système de propulsion (50), le moyen de commande (80) étant en communication avec le circuit de réfrigération (90) et étant programmé de sorte à ajuster le circuit de réfrigération en réponse à la température détectée de l'habitacle (20) et à la condition détectée du véhicule (10) ; dans lequel le moyen de commande (80) est programmé de sorte à réduire une vitesse d'au moins un dispositif, du premier dispositif de déplacement d'air (115), du deuxième dispositif de déplacement d'air (120) et du compresseur (110), en réponse à la détection d'une première condition du véhicule (10), et dans lequel le moyen de commande (80) est programmé de sorte à accroître la vitesse d'au moins un dispositif, du premier dispositif de déplacement d'air (115), du deuxième dispositif de déplacement d'air (120) et du compresseur (110), ayant été actionné auparavant à une vitesse réduite, en réponse à la détection d'une deuxième condition du véhicule (10) ; et dans lequel la première condition du véhicule

- englobe la porte (35) détectée comme se trouvant dans une position ouverte, la deuxième condition du véhicule englobant la porte (35) détectée comme se trouvant dans une position fermée. 5
2. Système HVAC selon la revendication 1, dans lequel la première condition du véhicule englobe en outre l'emplacement du véhicule (10), détecté comme étant situé à proximité étroite d'une structure auto-portante, la deuxième condition du véhicule englobant l'emplacement du véhicule (10) détecté comme étant situé au moins à une distance pré-déterminée de la structure autoportante. 10
3. Système HVAC selon la revendication 1, dans lequel la première condition du véhicule englobe en outre la charge du système de propulsion, détectée comme étant supérieure à une première valeur pré-déterminée, la deuxième condition du véhicule englobant la charge du système de propulsion, détectée comme étant inférieure à une deuxième valeur pré-déterminée. 15
4. Système HVAC selon la revendication 1, dans lequel le moyen de commande (80) est programmé de sorte à initialiser un délai pré-déterminé en réponse à la deuxième condition du véhicule et avant l'accroissement de la vitesse d'au moins un dispositif, du premier dispositif de déplacement d'air (115), du deuxième dispositif de déplacement d'air (120) et du compresseur (110), ayant été actionné auparavant à une vitesse réduite. 20
5. Système HVAC selon la revendication 1, dans lequel le véhicule (10) englobe un capteur d'un système de localisation GPS. 25
6. Système HVAC selon la revendication 1, dans lequel le moyen de commande (80) est programmé de sorte à initialiser un délai pré-déterminé en réponse à la condition du véhicule et avant l'accroissement de la vitesse d'au moins un dispositif, du premier dispositif de déplacement d'air (115), du deuxième dispositif de déplacement d'air (120) et du compresseur (110). 30
7. Système HVAC selon la revendication 1, dans lequel le moyen de commande (80) est programmé de sorte à accroître la vitesse d'au moins un dispositif, du premier dispositif de déplacement d'air (115), du deuxième dispositif de déplacement d'air (120) et du compresseur (110), indépendamment de la condition du véhicule, en réponse à une pression du réfrigérant du circuit de réfrigération détectée comme étant supérieure à une pression pré-déterminée. 35
8. Procédé d'actionnement d'un véhicule (10), le procédé comprenant les étapes ci-dessous : 40
- fourniture d'un habitacle (20) et d'un système de chauffage, de ventilation et de conditionnement d'air (« HVAC ») (75) dans le véhicule, le système HVAC englobant un circuit de réfrigération (90), servant à contrôler la température dans l'habitacle (20), sur la base d'une température détectée dans l'habitacle (20), le circuit de réfrigération (90) comportant un échangeur de chaleur externe (100), un premier dispositif de déplacement d'air (115), pour diriger l'air à travers l'échangeur de chaleur externe, un échangeur de chaleur interne (105), en communication de fluide avec l'échangeur de chaleur externe, un deuxième dispositif de déplacement d'air (120), pour diriger l'air à travers l'échangeur de chaleur interne, et un compresseur (110) ; initialisation du système HVAC (75) ; détection d'une condition du véhicule (10), englobant la détection d'au moins un critère, une position d'une porte (35) du véhicule, un emplacement du véhicule et une charge du système de propulsion du véhicule (50), une première condition du véhicule englobant la porte (35) détectée comme se trouvant dans une position ouverte, et la deuxième condition du véhicule englobant la porte, détectée comme se trouvant dans une position fermée ; ajustement du circuit de réfrigération (90) en réponse à la température détectée dans l'habitacle (20) et à la condition détectée du véhicule (10) ; réduction d'une vitesse d'au moins un dispositif, du premier dispositif de déplacement d'air (115), du deuxième dispositif de déplacement d'air (120) et du compresseur (110), en réponse à la détection de la première condition du véhicule (10) ; et accroissement de la vitesse d'au moins un dispositif, du premier dispositif de déplacement d'air (115), du deuxième dispositif de déplacement d'air (120) et du compresseur (110), ayant été auparavant actionné à une vitesse réduite en réponse à la détection de la deuxième condition du véhicule (10). 45
9. Procédé selon la revendication 8, comprenant en outre l'étape de réduction d'un bruit émis par le système HVAC (75) en réduisant une vitesse du circuit de réfrigération (90) en réponse à la condition du véhicule. 50
10. Procédé selon la revendication 8, comprenant en outre les étapes ci-dessous : 55
- détection de l'emplacement du véhicule (10) par rapport à une structure autoportante ; réduction d'une vitesse du circuit de réfrigération (90) en réponse à l'emplacement du véhi-

cule (10), détecté comme étant situé à proximité étroite de la structure autoportante ;
accroissement de la vitesse du circuit de réfrigération (90) en réponse à l'emplacement du véhicule (10), détecté comme étant situé au moins à une distance prédéterminée de la structure autoportante. 5

11. Procédé selon la revendication 8, comprenant en outre l'étape de réduction de la vitesse d'au moins un dispositif, du premier dispositif de déplacement d'air (115), du deuxième dispositif de déplacement d'air (120) et du compresseur (110) en réponse à la condition du véhicule. 10

15

12. Procédé selon la revendication 8, comprenant en outre les étapes ci-dessous :

détection d'une pression du réfrigérant du circuit de réfrigération (90) ; et 20
actionnement du circuit de réfrigération (90) à la vitesse à pleine capacité, indépendamment de la condition du véhicule, en réponse à la pression du réfrigérant détectée comme étant supérieure à une pression prédéterminée. 25

13. Procédé selon la revendication 8, comprenant en outre les étapes ci-dessous :

réduction de la vitesse du circuit de réfrigération (90) en réponse à la condition du véhicule ; et 30
accroissement de la vitesse du circuit de réfrigération (90) en réponse à une condition additionnelle du véhicule (10). 35

14. Procédé selon la revendication 13, comprenant en outre l'étape d'initialisation d'un délai prédéterminé en réponse à la condition additionnelle du véhicule et avant l'accroissement de la vitesse du circuit de réfrigération (90). 40

15. Procédé selon la revendication 8, comprenant en outre les étapes ci-dessous :

détection d'une charge du système de propulsion (50) ; 45
réduction d'une vitesse du circuit de réfrigération (90) en réponse à la charge du système de propulsion (50) détectée comme étant supérieure à une première valeur prédéterminée ; et 50
accroissement de la vitesse du circuit de réfrigération (90) en réponse à la charge du système de propulsion (50) détectée comme étant inférieure à une deuxième valeur prédéterminée.

55
